1 INTRODUCTION

Knight Piésold (Pty) Ltd was appointed by AngloGold Ashanti to conduct a specialist assessment of the floodlines associated with all the significant streams running through the existing Navachab Mine in Namibia.

The report is based on a review of available data including survey data and rainfall records provided by the Client. The report provides baseline information, assesses potential impacts, and recommends mitigation measures, where appropriate.

The main objective of this report is to determine the 1:50 and 1:100 year floodlines of the natural stream that flows through the Navachab Mine.

1.1 Aims

The aims of this report were:

- **Flood Hydrology Assessment:** To determine the 1:10, 1:20, 1:50 and 1:100 year flood peaks for the streams that flow through the project area, using both deterministic and empirical methods;
- **Floodline Development.** Use HEC-RAS software to determine the flood inundation area for all the significant streams running through the project area; and
- **Mitigation:** Development of flood alleviation measures to reduce impact of flooding.

2 FLOOD HYDROLOGY ASSESSMENT

The methods chosen to determine the flood discharges were both deterministic (The Rational method and Synthetic Unit Hydrograph method) and empirical (Regional Maximum Flood method). These models are built into the Utility Programs for Drainage Software (UPD) which has been used for the flood determination. The calculation of design floods requires the evaluation of the catchment runoff characteristics and return period storm rainfall depths.

2.1 Catchment Characteristics

The total catchment area, contributing to the runoff in the project area, is 308.085 km². There are three significant streams flowing through the project area. Stream A flows through the project area to the north of the plant, Stream B flows between the plant and the pit and Stream C runs to the south west of the pit. These three streams have an number smaller tributaries, of which eight have been identified as significant for the purposes of this study. The catchment areas are shown in Figure 2.1 and **Appendix A**.

All the runoff that passes through the project area flows into the Kahn river. Each of the eleven streams will be evaluated for the purposes of the determining both the flood peaks and the floodlines. The catchment characteristics of the eleven stream catchments are summarised in Table 2.1. Catchments D and E were not analysed as the streams are not covered by the detailed survey data and the streams only pass through a small remote section of the project area, located far away from the plant and pit.

Table 2.1 : Catchment Characteristics

Catchment	Catchment Area (km ²)	Longest Flowpath (km)	Average Slope (m/m)	Distance to Centroid (km)
A	9.369	7.335	0.0064	3.555
B1	23.709	12.290	0.0102	5.670
B2	30.700	22.768	0.0082	14.268
B3	14.210	3.320	0.0118	4.948

C6	4.080	2.700	0.0019	1.187

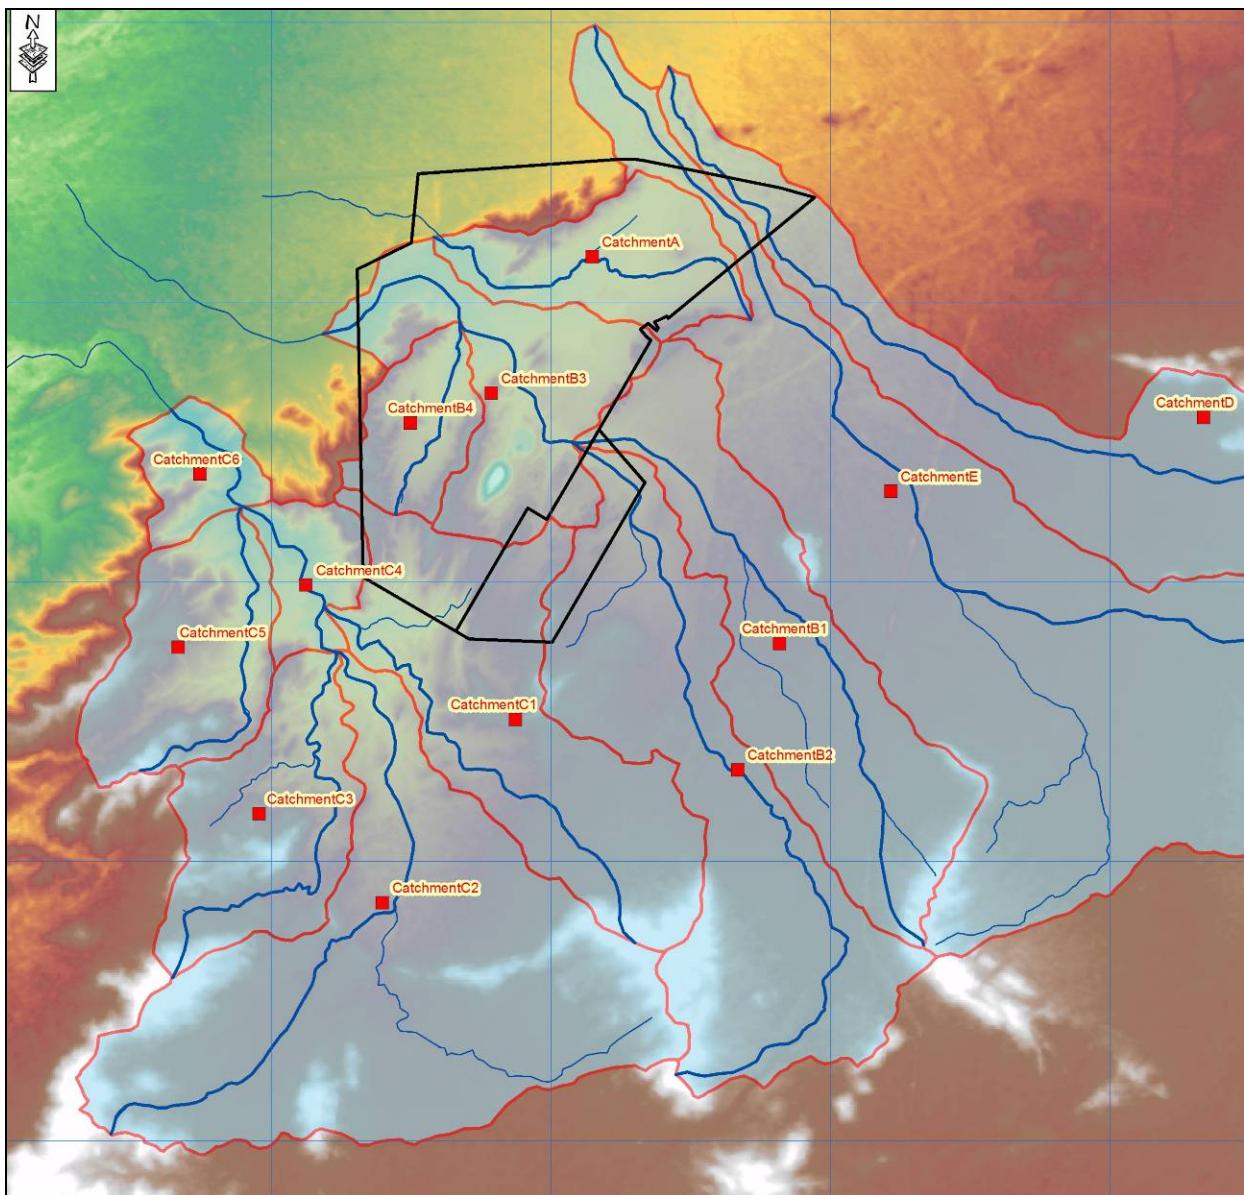

Figure 2.1 : Significant streams, tributaries and sub-catchment areas

2.2 Rainfall Information

It was very difficult to directly estimate the 1:50 and 1:100 year rainfall based on the limited rainfall data, received from the Client. Essentially we received 19 years of monthly rainfall records for the rainfall station located at the Navachab Mine.

Based on the monthly data, its clear that the majority of the rainfall falls between December and March but the data does not allow any insight into daily rainfall events, which are necessary in determining the 1:50 and 1:100 year 24hr point precipitation.

The rainfall data provided by the Client was substituted with the daily rainfall records obtained from a nearby station located 12 km form the project area in the town of Karibib.

The rainfall station 826596 at Karibib was chosen as the most reliable due to the length of its record (32 years). There is another rainfall station at Usakos, but it was not considered as it only has 28 years of record and is located further away from the site. The rainfall data for the chosen station is presented in Table 2.2 and Table 2.3.

Table 2.2 : Characteristics of Rainfall Station - 826596

Rainfall Station	Mean Annual Precipitation (mm)	Record (years)
826596	269	32

Table 2.3 : Design Rainfall for Station - 740154

Duration (Days)	Return Period (years)						
	2	5	10	20	50	100	200
1 day	32	49	63	78	102	123	146
2 days	40	60	74	91	116	139	170
3 days	42	68	89	114	153	189	234
7 days	50	83	111	142	195	245	308

63 mm, 78 mm, 102 mm and 123 mm were used to determine the 1:10, 1:20, 1:50 and 1:100 year flood events respectively.

3 FLOOD PEAK DETERMINATION

3.1 Rational Method

The Rational method uses the depth-duration-return period diagram to determine point precipitation in the catchment. The Rational method, primarily applied to small catchments (15 to 25 km²), has been found to give good results for catchments up to 500 km².

The Rational method uses the following equation to determine the run-off from the catchment:

$$Q = \frac{C.I.A}{3.6} \quad \text{Equation 1}$$

Where Q = Peak Flow (m³/s)
 C = runoff coefficient
 I = Rainfall Intensity (mm/hr)
 A = Catchment Area (km²)

A runoff coefficient of 0.399 has been assumed for catchment area. The runoff coefficient is based on surface slopes, permeability and vegetation. The rainfall intensity (mm/hr) is the point precipitation (mm) divided by the time of concentration (hr).

The streams running through the project area are considered ephemeral and only tend to flow after spate rainfall events. The infrequent flows supports the use of the overland equation in determining the time of concentration.

$$T_c = 0.604 \left(\frac{rL}{S^{0.5}} \right)^{0.467} \quad \text{Equation 2}$$

Where T_c = Time of Concentration (hrs)
 r = Roughness coefficient (0.25 – 0.30)
 L = Longest Flowpath (km)
 S = Average Catchment Slope (m/m)

Longest flowpath is the longest distance that water would follow from the furthest point in the catchment to the end of the flowpath.

The results of the flood hydrology determination is summarised in Table 3.1.

Table 3.1 : Flood Peaks calculated using the Rational Method

Catchment Area	Flow Rate (m ³ /s)			
	1:10 yr	1:20 yr	1:50 yr	1:100 yr
A	10.5	13.7	18.8	24.4
B1	23.7	31.0	42.3	54.6
B2	23.2	30.3	41.4	53.5
B3	23.8	31.1	42.5	54.9
B4	9.1	11.9	16.3	21.1
C1	27.8	36.3	49.6	63.9
C2	36.0	47.0	64.2	82.8
C3	15.6	20.4	27.9	36.1
C4	7.0	9.2	12.6	16.3
C5	18.2	23.7	32.5	42.0
C6	5.3	6.9	9.5	12.3

3.2 Alternative Rational Method

This method is an adaptation of the traditional Rational method shown Section 3.1.

The main difference lies in the method used to calculate the point precipitation. The Rational method uses the depth-duration-return period diagram to determine point precipitation, whilst the alternative method uses the modified recalibrated Hershfield equation for short durations (less than 6 hours) and actual design rainfall (Smithers and Schulze, 2001) for durations of 1 to 7 days (South African National Roads Agency, 2006). The results are shown in Table 3.2.

Table 3.2 : Flood Peaks calculated using the Alternative Rational Method

Catchment Area	Flow Rate (m ³ /s)			
	1:10 yr	1:20 yr	1:50 yr	1:100 yr
A	15.6	20.4	27.0	32.8
B1	35.6	46.6	61.5	74.6
B2	35.1	45.9	60.7	73.6
B3	35.3	46.1	60.9	73.9
B4	13.4	17.5	23.2	28.1
C1	41.4	54.2	71.7	86.9
C2	53.6	70.1	92.7	112.4
C3	23.2	30.3	40.1	48.6
C4	10.3	13.5	17.8	21.6
C5	26.8	35.1	46.4	56.3
C6	7.8	10.2	13.5	16.4

3.3 Unit Hydrograph Method

A unit hydrograph is a characteristic of a specific catchment and is defined as the hydrograph of 1mm of runoff (excess rain), following rainfall of unit duration, with uniform spatial and time distribution over the catchment. Hence the duration of the hydrograph is proportional to the duration of the rainfall and the volume proportional to the intensity of the rainfall (Van der Spuy et al, 2004).

Unit hydrographs from numerous flow gauging stations in South Africa were compiled from historical data. From this data, synthetic hydrographs for 9 regions of South Africa have been derived. These 9 regions have similar catchment characteristics such as topography, soil type, vegetation type and rainfall characteristics. The catchment in question belongs to veld type zone 4.

The Synthetic Unit Hydrograph (SUH) method is applicable to catchments of size range $15\text{km}^2 - 5000\text{km}^2$. The SUH method as implemented in UPD was used to determine the flood peak discharge for the same range of return periods. The results are summarised in Table 3.3.

Table 3.3 : Flood Peaks calculated using the SUH Method

Catchment Area	Flow Rate (m^3/s)			
	1:10 yr	1:20 yr	1:50 yr	1:100 yr
A	15.7	22.2	33.8	47.0
B1	30.2	42.5	64.4	88.9
B2	29.8	41.8	63.6	87.5
B3	27.4	38.8	59.1	82.0
B4	11.2	15.9	24.3	33.8
C1	35.3	49.6	75.2	103.8
C2	46.9	65.7	99.2	136.5
C3	21.6	30.6	46.5	64.6
C4	8.7	12.4	19.0	26.4
C5	23.2	32.8	50.1	69.7
C6	8.3	11.8	18.0	25.1

3.4 Empirical Flood Peak Estimate

The Regional Maximum Flood (RMF) (Kovacs, 1988) approach was developed for Southern Africa in the late 1980's and with time has proved to produce good estimates of flood peak discharges.

Kovacs (1988) adopted the methodology by Francou and Rodier (Hydrological Services of Electricité de France) for Southern African conditions.

The Francou Rodier Formula is given as:

$$\frac{Q}{Q_0} = \left(\frac{A}{A_0} \right)^{1-0.1x} \quad \text{Equation 3}$$

Where:
 Q = Required Flood Peak (m^3/s)
 Q_0 = Mean Annual Runoff of all the rivers in the world ($10^6 \text{ m}^3/\text{s}$)
 A = Catchment area (km^2)
 A_0 = Total drainage area on earth (10^8 km^2) (excl deserts and polar regions)
 K = Regional characteristic coefficient

Kovacs based the K values for Southern Africa on maximum flood peaks recorded at various sites in South Africa and neighbouring countries. Eight maximum flood peak regions were identified based on rainfall, catchment characteristics and recorded flood peaks. The RMF is calculated using the Francou-Rodier formula on the basis of the catchment area and a regional K factor. For the project area, the applicable K factor is 4.0. Table 3.4 gives scaled RMF flood peak values.

Table 3.4 : Flood Peaks calculated using the RMF Method

Catchment Area	Flow Rate (m^3/s)			
	1:10 yr	1:20 yr	1:50 yr	1:100 yr
A	12.8	17.4	24.1	30.5
B1	23.1	31.4	43.5	55.2
B2	20.5	27.8	38.5	48.8
B3	20.8	28.3	39.1	49.7
B4	11.6	15.8	21.8	27.7
C1	25.3	34.4	47.7	60.5
C2	29.3	39.8	55.2	70.1
C3	16.6	22.5	31.2	39.6
C4	9.3	12.6	17.5	22.2
C5	18.8	25.6	35.4	45.0
C6	8.8	12.0	16.6	21.1

4 FLOOD ASSESSMENT

The flood peaks determined using the Rational, Alternative Rational, Synthetic Unit Hydrograph (SUH) and RMF methods are summarised in Table 4.1 and Table 4.2.

Table 4.1 : 1:50 year Flood Peak Summary

Catchment	Flood Peak (m ³ /s)				
	Rational	Alt Rational	SUH	RMF	Recommended
A	18.8	27.0	33.8	24.1	30.40
B1	42.3	61.5	64.4	43.5	62.95
B2	41.1	60.7	63.3	38.5	62.00
B3	42.5	60.9	59.1	39.1	60.00
B4	16.3	23.2	24.3	21.8	23.75
C1	49.6	71.7	75.2	47.7	73.45
C2	64.2	92.7	99.2	55.2	95.95
C3	27.9	40.1	46.5	31.2	43.30
C4	12.6	17.8	19.0	17.5	18.40
C5	32.5	46.4	50.1	35.4	48.25
C6	9.5	13.5	18.0	16.6	15.75

Table 4.2 : 1:100 year Flood Peak Summary

Catchment	Flood Peak (m ³ /s)				
	Rational	Alt Rational	SUH	RMF	Recommended
A	24.4	32.8	47.0	30.5	39.90
B1	54.6	74.6	88.9	55.2	81.75
B2	53.5	73.6	87.5	48.8	80.55
B3	54.9	73.9	82.0	49.7	77.95
B4	21.1	28.1	33.8	27.7	30.95
C1	63.9	86.9	103.8	60.5	95.35
C2	82.8	112.4	136.5	70.1	124.45
C3	36.1	48.6	64.6	39.6	56.60
C4	16.3	21.6	26.4	22.2	24.00
C5	42.0	56.3	69.7	45.0	63.00
C6	12.3	16.4	25.1	21.1	20.75

The RMF is an empirical method and the flood peak is based on regional information. This method is useful for evaluating results obtained using more rigorous methods or where data is not sufficient to use the more rigorous methods. The RMF is noted for producing less

conservative estimates for smaller catchments and is therefore not representative for small catchments ($<30\text{km}^2$).

Generally, SUH results are higher than the equivalent Rational results for smaller catchments. The SUH is usually applied to medium to large catchments ($>15\text{km}^2$) and is therefore only suitable for certain catchments. The Rational methods are more applicable to smaller catchment sizes and produce conservative results.

The Alternative Rational method is based on rainfall data applicable to the project area and is favoured over the Rational method. It is suggested that the average value of the Alternative Rational method and the SUH method be adopted for the 1:50 and 1:100 year design floods for all the catchments areas less than 15km^2 and the average value of the be adopted for catchment areas greater than 15km^2 ; namely catchments B1, B2, C1 and C2. This is considered a reasonable approach providing suitably conservative results.

DRAFT

5 FLOOD INUNDATION LINES

The 1:50 year and 1:100 year flood inundation lines were prepared using the HEC-RAS software. The primary input to HEC-RAS is the cross section information that describes the shape and slope of the stream, and the channel roughness. The HEC-RAS cross section plans are presented in **Appendix D**.

Cross sections were prepared from the LiDAR survey of the area using the HEC-GEORAS interface. Three sets of survey data were used to develop a surface containing the project area and the contributing catchment area. The combined survey mapping is presented in **Appendix B**.

The channel roughness coefficient, required by the HEC-RAS software was estimated at 0.035. HEC-RAS is a backwater programme based on the Mannings' equation. The programme determines the flow depth and velocities at the cross-sections. The results obtained from HEC-RAS, for the seven stream sections are summarised in **Appendix E**.

The analysis results were then exported to ArcView, which was used to prepare the flood inundation maps of the project area. The 1:50 and 1:100 year floodlines are presented in **Appendix C**.

The flood inundations areas for the 1:50 year and 1:100 year floods are not significantly different. The wide stream channel and defined banks results in a very small rise in the water level. This results in a very small increase in the inundation areas between the two flood events.

6 POTENTIAL MITIGATION MEASURES

The floodline assessment has identified that significant areas of the project area lie within the 1:50 and 1:100 year flood inundations areas, as presented in **Appendix C**. Flood mitigation involves managing the effects of this flooding, rather than trying to prevent it altogether.

The purpose of this investigation was to determine the extent of the possible flooding, and then propose alternatives to alleviate the impact of potential flooding.

Stream diversion, culverts, stormwater pipes, diversion berms and attenuation dams are some of the planning controls that can be used to assist with flood protection for developments within the flood inundation area. All flood attenuation facilities should be designed to provide control for a 1:50 and/or 1:100 year flood.

Unlined trapezoidal diversion canals, running along the perimeter of the plant and pits, can be designed to contain the 1:50 year floods and thereby eliminate flooding. Diversion berms are another alternative to containing flood waters. These approaches can be developed at Navachab mine to reduce the impact of flooding.

6.1 Diversion Canals

Simple unlined trapezoidal diversion canals can be constructed around the existing plant and pits. The canals will divert the flow around the site and then discharge back into the natural channel.

The hydraulic design of the unlined trapezoidal diversion canals will ensure that the canal operates under stable, sub-critical flow conditions where possible. The stable, sub-critical flow conditions will limit erosion of the canal. To achieve this, Froude numbers of less than 0.7 are necessary.

Canal A (red line) runs around the northern pit and tailings dam as shown in Figure 6.1. Canal B1 (green line) runs north around the plant and the Canal B2 (green line) runs south around the pit. Both canals will divert the runoff from catchments B1 to B4 around the plant and pit before returning to the original river alignment as shown in Figure 6.2.

An additional canal may be constructed along the alignment of Stream C. The canal will sized to accommodate the entire runoff from catchments C1 to C6, thus resulting in no floodlines. This canal should be developed in accordance with the future development of the mine.

Figure 6.1 : Proposed Canal A alignment

Figure 6.2 : Proposed Canal B1 and B2 alignments

The design parameters of the proposed unlined trapezoidal canals are as follows:

- Unlined trapezoidal drains with 1V: 3H side slopes;
- Unlined drain Mannings' n = 0.030;
- Drain slopes = 1 : 200; and
- Drain depth = flow depth + 10% allowance for groundwater + 300mm freeboard (Sub-critical flow conditions).

Flow depth was calculated using the Mannings' equation:

$$Q = \frac{AR^{2/3}S^{1/2}}{n}$$

Equation 3

Where Q = Peak Flow (m^3/s)

A = Cross Section Flow Area (m^2)

R = Hydraulic Radius (m)

S = Canal Slope (m/m)

n = Mannings' n value (0.030)

The above equation was manipulated to solve for flow depth. Preliminary canal sizes were calculated for the canals associated with streams A and B. The results are presented in **Table 6.1** and **Table 6.2**.

Table 6.1 : Diversion Canal sizes for the 1:50 yr flood events

Canal Sections	Flowrate	Base Width	Flow Depth	Flow Velocity	Total Depth	Top Width
	m^3/s	m	m	m/s	m	m
Canal A	30.00	5.00	2.196	2.415	2.715	6.464
Canal B1	65.00	10.00	2.187	2.770	2.705	11.458
Canal B2	68.00	10.00	2.251	2.811	2.776	11.500

Table 6.2 : Diversion Canal sizes for the 1:100 yr flood events

Canal Sections	Flowrate	Base Width	Flow Depth	Flow Velocity	Total Depth	Top Width
	m^3/s	m	m	m/s	m	m
Canal A	40.00	5.00	2.614	2.600	3.175	6.742
Canal B1	85.00	10.00	2.595	3.014	3.155	11.730
Canal B2	88.00	10.00	2.653	3.047	3.219	11.769

6.2 Diversion Culvert

Alternatively, a single canal (orange line) can be developed for Stream B, following the original stream alignment, incorporating a diversion culvert. This will allow the canal to pass between the plant and the pit. The proposed alignment is illustrated in Figure 6.3.

Figure 6.3 : Proposed canal and culvert alignment for Stream B

Using the same design approach adopted in Section 6.1, the hydraulic results for the single canal B incorporating a diversion culvert is presented in Table 6.3.

Table 6.3 : Diversion Canal B sizes for the 1:50 and 1:100 yr flood events

Flood Event	Flowrate	Base Width	Flow Depth	Flow Velocity	Total Depth	Top Width
	m ³ /s	m	m	m/s	m	m
1:50 yr	133.000	15.00	2.601	3.223	3.161	16.734
1:100 yr	173.000	15.00	3.073	3.513	3.681	17.049

7 CONCLUSIONS AND RECOMMENDATIONS

The flood inundation areas for the 1:50 and 1:100 year flood events are not significantly different. This is due to the nature of the stream channel. The cross sections indicate a wide channel with clearly defined banks on either side. The water levels for the 1:50 and 1:100 year flood events rise by a small amount, which is contained within the stream channel. This results in very little change in the inundation areas.

It is clearly evident from the floodline mapping (see **Appendix C**) that the existing mining infrastructure is located within the flood inundation areas. This poses a significant risk to both the infrastructure as well as the downstream environment.

In order to minimise the impact of the flooding, mitigation measures were proposed. The mitigation measures included the development of adequately sized diversion canals throughout the project area. The proposed diversion canals have been sized to safely contain the 1:50 and 1:100 year flood events. By developing the diversion canals, the flood runoff is channelled through the project area in a contained and controlled manner. The diversion strategy has been developed to manage the flow of stormwater through the site.
